Exercise - Configure an App Service

5 minutes

This module requires a sandbox to complete. A [sandbox](#) gives you access to Azure resources. Your Azure subscription will not be charged. The sandbox may only be used to complete training on Microsoft Learn. Use for any other reason is prohibited, and may result in permanent loss of access to the sandbox.

Due to the impact of the global health pandemic, Azure resources are being prioritized towards health and safety organizations. You may experience some issues when you deploy resources used in the exercises. Please try again or choose a different region. For more information, see Azure blog post - [March 28: Update #2 on Microsoft cloud services continuity](#).

[Activate sandbox](#)

Recall from earlier, that we're using an App Service to run our WordPress application. Here we'll look at additional information exposed about our application and explore some of the available options to configure our website.

Let's have a look at some of this information.

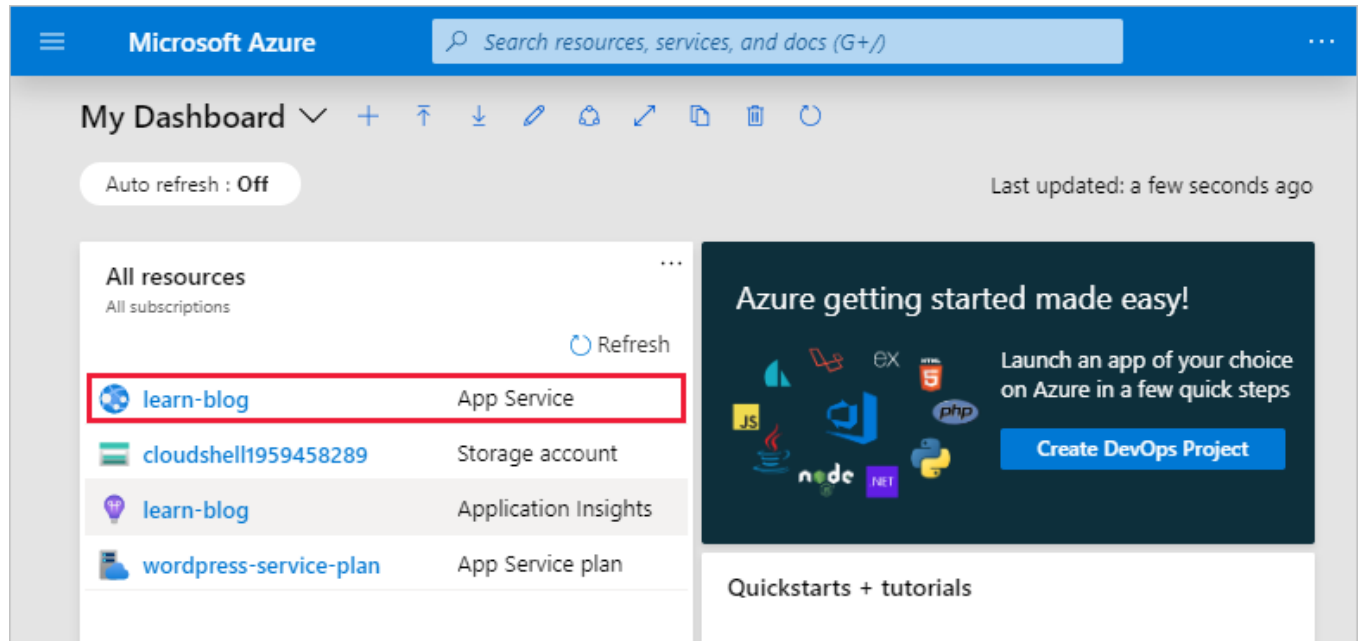

1. Open the [Azure portal](#) .
2. From the left-hand navigation menu, select **Dashboard** to access a list of all resources in your subscription. You may have to click the menu icon to show the navigation choices.

The screenshot shows the Microsoft Azure My Dashboard. At the top, there's a blue header with the Microsoft Azure logo and a search bar. Below the header, the dashboard is titled "My Dashboard" with a dropdown arrow and several icons. A toggle for "Auto refresh : Off" is visible, along with a timestamp "Last updated: a few seconds ago".

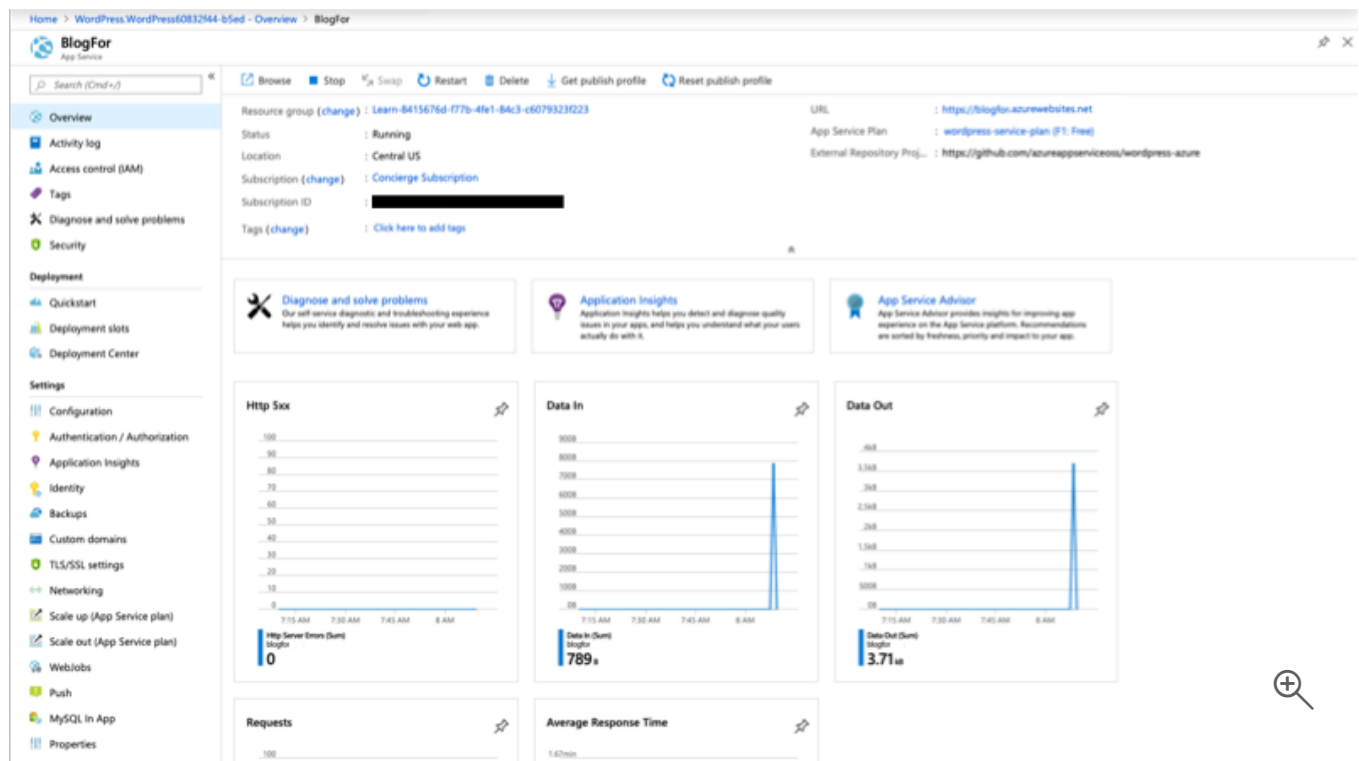

The main content area is divided into several sections:

- All resources**: A list of resources under "All subscriptions". It includes:
 - learn-blog** (App Service)
 - cloudshell1959458289** (Storage account)
 - learn-blog** (Application Insights)
 - wordpress-service-plan** (App Service plan)A "Refresh" button is located at the top right of this section.
- Azure getting started made easy!**: A dark blue banner with various technology logos (JS, EX, PHP, node, .NET, etc.) and a button that says "Create DevOps Project".
- Quickstarts + tutorials**: A list of quickstarts and tutorials:
 - Windows Virtual Machines**: Provision Windows Server, SQL Server, SharePoint VMs.
 - Linux Virtual Machines**: Provision Ubuntu, Red Hat, CentOS, SUSE, CoreOS VMs.
 - App Service**: Create Web Apps using .NET, Java, Node.js, Python, PHP.
 - Functions**: Process events with a serverless code architecture.
 - SQL Database**: Managed relational SQL Database as a Service.
- Service Health** and **Marketplace**: Two buttons at the bottom left.

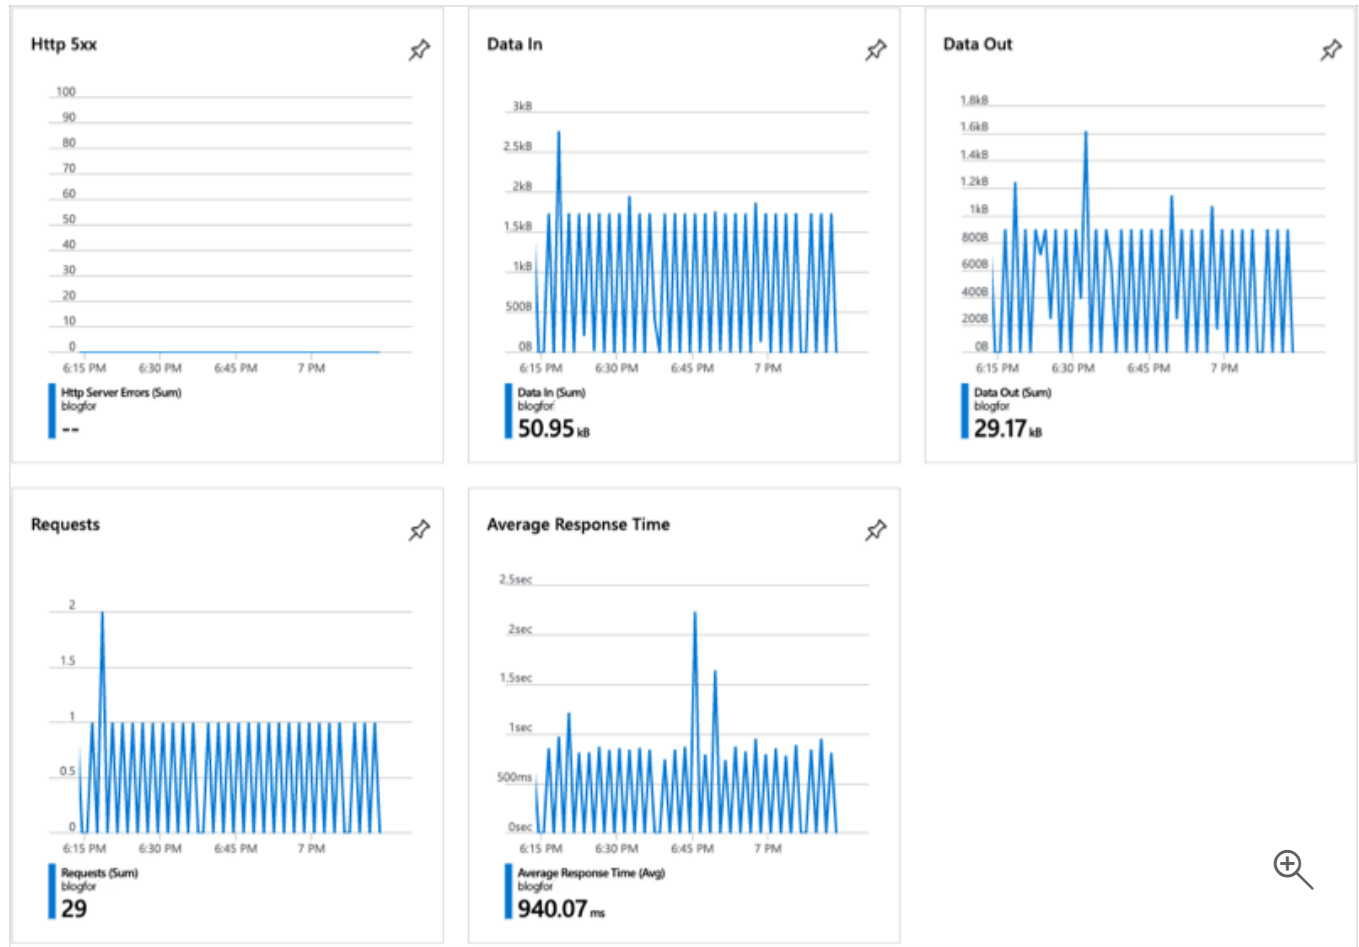

3. Select the **App Service** with the name you chose it in the previous exercise.

4. By default, the app service's overview is displayed, if not select **Overview**.

5. Scroll down in the overview view to where you can see the graphs for your newly created website. These graphs provide statistics about the number of requests received by our website, the amount of data in, data out, and the number of errors encountered on the site.

The information displayed here is near real-time data and gives a quick overview of the performance of your website. Problems with the site's performance will manifest in these graphs as early warnings.

What is scale?

Suppose you deployed your website and it becomes popular. By looking at the graphs in the overview, you realize that your site can't effectively manage all the requests it's receiving. To solve the problem, you'll need to increase the server's hardware capacity.

Scale refers to adding network bandwidth, memory, storage, or compute power to achieve better performance.

You may have heard the terms *scaling up* and *scaling out*.

Scaling up, or vertical scaling means to increase the memory, storage, or compute power on an

existing virtual machine. For example, you can add additional memory to a web or database server to make it run faster.

Scaling out, or horizontal scaling means to add extra virtual machines to power your application. For example, you might create many virtual machines configured in exactly the same way and use a load balancer to distribute work across them.

Tip

The cloud is elastic. You could *scale down* or *scale in* your deployment if you needed to scale up or scale out only temporarily. Scaling down or scaling in can help you save money. **Azure Advisor** and **Azure Cost Management** are two services that help you optimize cloud spend. You can use these services to identify where you're using more than you need, and then scale back to the capacity you're actually using.

When you have more time, feel free to go through each section and explore the various options available.

How to change the App Service configuration

The App Services has many configurable options available and groups these options in sections of functionality.

The first section displayed is a group of common options you'd access to get a view of the health of your application. However, each following section provides additional functionality and information.

For example, the **Settings** section gives you access to configure various aspects such as application settings, backups, custom domains, TLS/SSL settings, options to scale up the resources of the application, and so on.

Settings

-  Configuration
-  Authentication / Authorization
-  Application Insights
-  Identity
-  Backups
-  Custom domains
-  TLS/SSL settings
-  Networking
-  Scale up (App Service plan)
-  Scale out (App Service plan)
-  WebJobs
-  Push
-  MySQL In App
-  Properties
-  Locks
-  Export template

Scale up your App Service

1. In the **Settings** configuration section for your app service, select **Scale up (App service plan)**.

2. Notice that there are three workload categories to choose from in the configuration pane. These three categories make it easier to decide the type of workload we'll run.

Category	Description
Dev / Test	This category is ideal for less demanding workloads. This category is predominantly focused on providing shared infrastructure. In this category, you have additional features that become available to the App Service application. For example, Custom domains / SSL and manual scale.
Production	This category is ideal for more demanding workloads. In this category, you'll also notice added features such as staging slots, daily backups, and a traffic manager.
Isolated	This category is ideal for workloads that require advanced networking and fine-grained scaling.

Within each category, there are pricing tiers that will allow us to scale the resources available to our App service. These pricing tiers give us access to the additional features mentioned above.

We'll leave the configuration on the **F1** tier, but know that this pane is where you can go to make scaling adjustments in your app service if you have changes in load for your application.

Let's now take a look at how to use the Cloud Shell to configure Azure resources, such as App Service.
